# My Shared Diary

Android Application Project

## Project Plan Document

Several thin, curved lines in dark blue and light grey originate from the left side and sweep upwards and to the right.

**Project Group:** PG2

**Team Members**

Chelle, Vishnu – 07

Arumalla, Chandra Mouli – 03

Lam, Sundar Sagar – 19

Salapaka, Phanideep – 28

## **I. Introduction**

The idea of this project comes from the question which each one of us encounter at some point of our daily life “What have I done during last week/month/someday?”, and we don’t have an answer. We believe- “Human brains are very powerful to remember almost everything that happens but humans are not that powerful to restore that information from brain”. Here comes the necessity of having some other system to track and store our daily activities. This was done traditionally from ages by writing a “Dairy” mostly at the end of day about the events of that day. But now with the busy modern work life, it is difficult to find time to sit and write about ourselves. But still we have to track ourselves right?

This gives us the motivation to create something which will be with us throughout most of our daily time and track out events. Now the question comes what we have to create? Based on our understanding on this modern world we are making this statement “Smartphone is almost a human body part.” This motivated us to consider smartphone to track our daily activities.

## **II. Project Goal and Objectives**

### **Overall goal:**

Our main goal is to build an android application [9] which will replace the traditional system of writing dairies in books. We know that this is not a new idea but our objective is to make a part of our personal dairies to get shared between communities. A user can share his/her info as private information which will remain on his time track also share some common events or info with his communities like friends and family. Objective is to track ones individual life based on timestamp and location as well as track daily events of the person based on communities like family.

### **Specific Objective:**

To be specific our objective is to answer two simple questions of an individual:

“What I have done in last month/week/specific date?” – Provide tracked input of user including metrics like travel, restaurants etc.

“What my community (e.g.: family) has done in last month/week/specific date?” – Provides all the shared information from the users belonging to a specific group.

## **III. Related Work**

We have a lot of applications available for storing notes and daily activities. Evernote [1], Private Dairy [2] and Personal Diary [3] are few applications that are in this category. Evernote [1] is generally thought of as a best-in-class note-taker. Mobile version is available for IOS, Android, Windows and blackberry platforms. Evernote allows users to store texts, images and voice notes. It stores the data on servers. The user can store data in their mobiles when offline and can sync it with the server later.

Private Dairy [2] is another application available for Android and Kindle platforms. This application allows us to store texts and images. It stores the data on the server. Users can also record data when offline and sync them with server later. Personal Dairy [3] and Daily Log [4] are few android applications which allows user to store texts and images. The user can store the data in his/her Dropbox.

The data stored in these apps is completely private and there is no option to create communities to share data. Our objective is to create a new android app to include the feature to create communities and share data along with the already existing ones. Also we are trying to perform background analytics based on the user input which will give better results for the user.

#### **IV. Proposed System**

##### **Functional/Non-functional Requirements:**

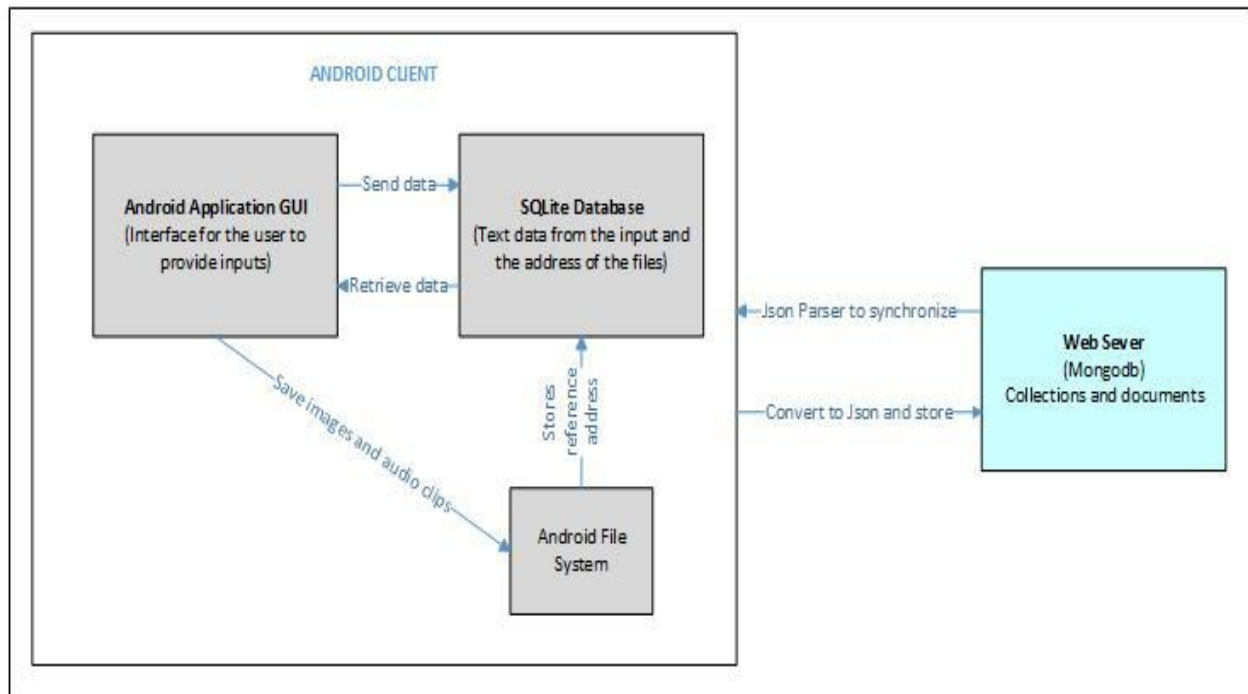

1. System will allow user to create an account which will be password protected.
  - a. Username will be the email ID of the user and will be unique.
  - b. Login through Facebook will be provided. However user should create new pin to make the app secure. Facebook API [5] will be integrated.
  - c. Password/pin will be encrypted and saved in the memory.
  - d. Other user details include basic details such as name, home/work address, phone number etc.
  - e. User details are saved in both client and the web server.
2. Each user will be able to create groups/communities to share a part of his daily information.
  - a. User will be able to create a community and invite others to join the community. The invitee should be a user of the system.
3. System will allow user to input his/her daily tasks of writing, daily events, images, audio.
  - a. A user friendly GUI will be developed to allow user to input the information.
  - b. All the information will be stored based on the time stamp.
4. When the user is inputting the data, the user will have option to choose whether the information is private or to share with specific community.
5. The input data will be stored in the phone memory (offline) and will be updated in the web server when the user is online. This feature will give the user to use the app offline.
  - a. A web server will be maintained which will have all the user details and the information. However user information is not encrypted in the server.
6. System will also provide a feature for the use to plan future tasks.
7. All the input posts are stored based on the timestamp and location which will allow the system to track the old data as well as to perform background analytics.
  - a. The system will save the location of the user in intermediate times and perform background analytics to calculate interesting results like the users travelling history. Google Maps API [6] and the Android framework Location API in the package android.location.
8. The system will also have feature to generate notifications to get inputs from the user in an easier way. For example if the user is at the same location for more time during lunch time the system will try to pop a notification "Are you having lunch? Where? (We are planning to suggest nearby locations as well)."
  - a. We will be using Google Maps API [6] integrated with Yelp API [7] for the suggestions.
9. We are planning to track the core daily activities of the user such as time waking up, time to sleep, food timings etc., to generate interesting analytics which can be presented back to the user.

- a. Yet to plan a design strategy on how to grab these details from the user in a simpler fashion.

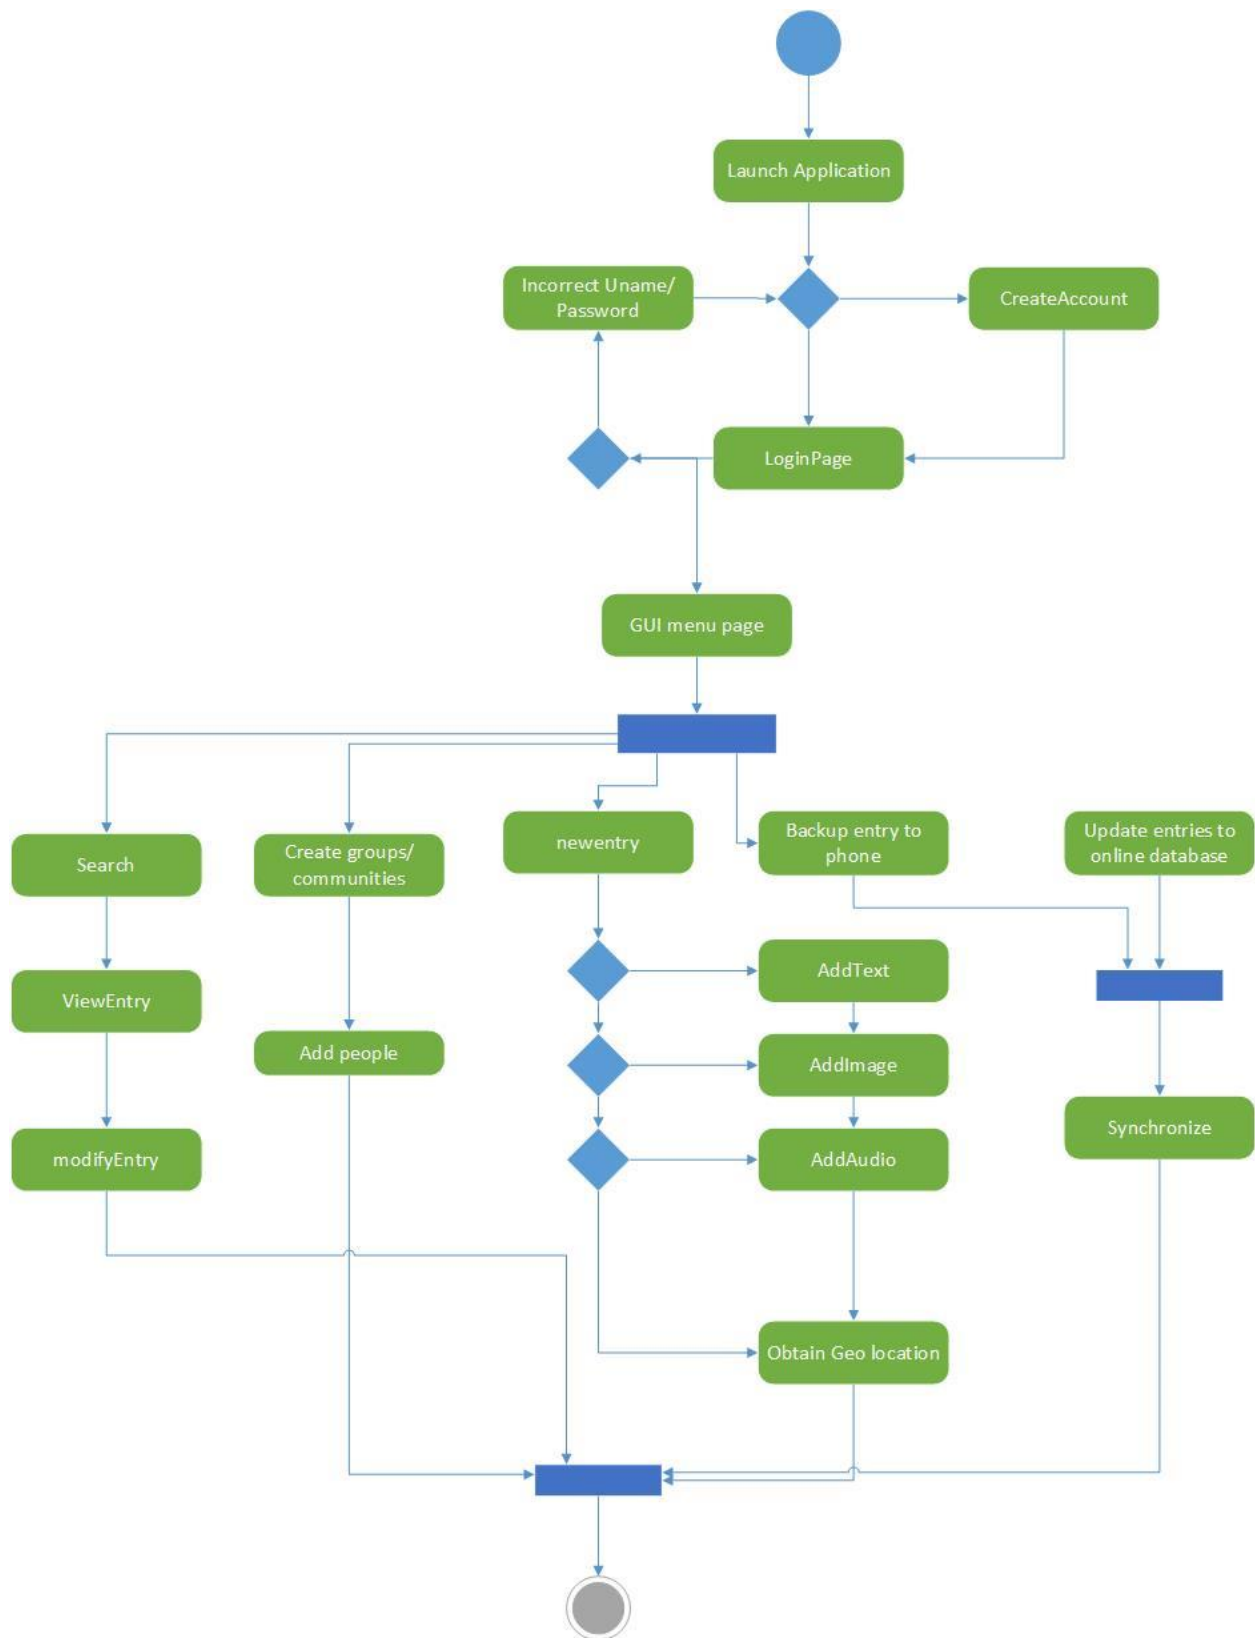

Note: Our future work for the project includes improving the current features as well as adding additional features in the new increments. Main goal of the project is to design the system for the above specifications. Our future work also includes developing a web GUI for the system.

### Overall System:

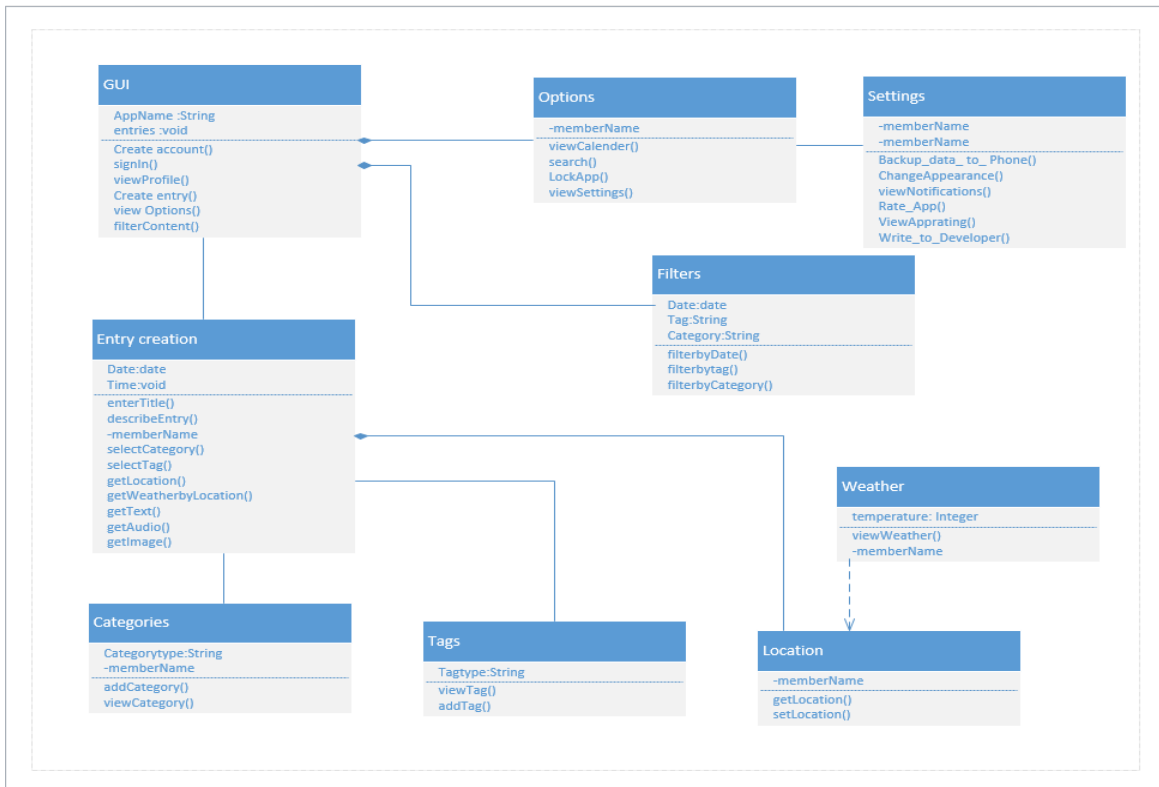

Overall system will comprise of Android client with the inbuilt SQL lite database and Webserver which is planned to be Mongodb [8]. The Android client will be always available to the user (even offline), and the data will be stored in the local phone db. Once internet is on, the local database and the server database will be synchronized. The server database will also synchronize the community data which is being shared with all the users in the community. In the web server data will be stored in the Jason format, mapped in similar with the SQLite database.
